

Global Temperature Record

Tim Osborn & Phil Jones

(this graph of HadCRUT4 is also available as [Encapsulated PostScript](#) and [PDF](#) suitable for publication and the data are available as [Comma-Separated Values](#))

The time series shows the combined global land and marine surface temperature record from 1850 to 2018. Last year (2018) was the fourth warmest on record using our latest analysis, referred to as HadCRUT4 (Morice *et al.*, 2012). The latest version of this analysis is HadCRUT4.6.

The period 2001-2010 (0.49°C above the 1961-1990 average) was 0.21°C warmer than the previous 1991-2000 decade. The current decade has warmed further: the average for 2011-2018 is 0.60°C above the 1961-1990 average and more than 0.90°C above the late 19th century average. The last four years are the warmest four in record: 2015 and 2016 are clearly the warmest years (0.76°C and 0.80°C, respectively), while 2018 is fourth warmest (0.60°C above the 1961-1990 average).

This time series is compiled jointly by the Climatic Research Unit and the UK Met Office Hadley Centre. Our work is undertaken under the auspices of the UK's National Centre for Atmospheric Science (NCAS) funded by the Natural Environment Research Council.

Increased concentrations of greenhouse gases in the atmosphere due to human activities are the dominant cause of the long-term warming observed since the 19th century. The warmth or coldness of individual years is strongly influenced by whether there was an El Niño or a La Niña event occurring in the equatorial Pacific Ocean.

The Intergovernmental Panel on Climate Change (IPCC) in its most recent assessment report in 2013 stated:

‘Warming of the climate system is unequivocal, and since the 1950s, many of the observed changes are unprecedented over decades to millennia. The atmosphere and ocean have warmed, the amounts of snow and ice have diminished, sea level has risen, and the concentrations of greenhouse gases have increased’

‘Human influence on the climate system is clear. This is evident from the increasing greenhouse gas concentrations in the atmosphere, positive radiative forcing, observed warming, and understanding of the climate system’

‘Human influence has been detected in warming of the atmosphere and the ocean, in changes in the global water cycle, in reductions in snow and ice, in global mean sea level rise, and in changes in some climate extremes. It is extremely likely that human influence has been the dominant cause of the observed warming since the mid-20th century’
